Concept

An active power filter is a large power electrical device that monitors the three-phase current in real time and provides an equally opposite phase to relevant devices to filter out the harmonics. It is connected in parallel to the grid and uses a current transformer to inspect the 3-phase current waveform and to obtain the required compensation data of harmonic current and reactive power. The active power filter will then inject an equally opposite current input to the power system for harmonic filtering. In addition, the active power filter can also create a phase that complements the leading and lagging reactive current. It effectively improves the power factor of the grid and provides compensation to the reactive power.
